

# #04

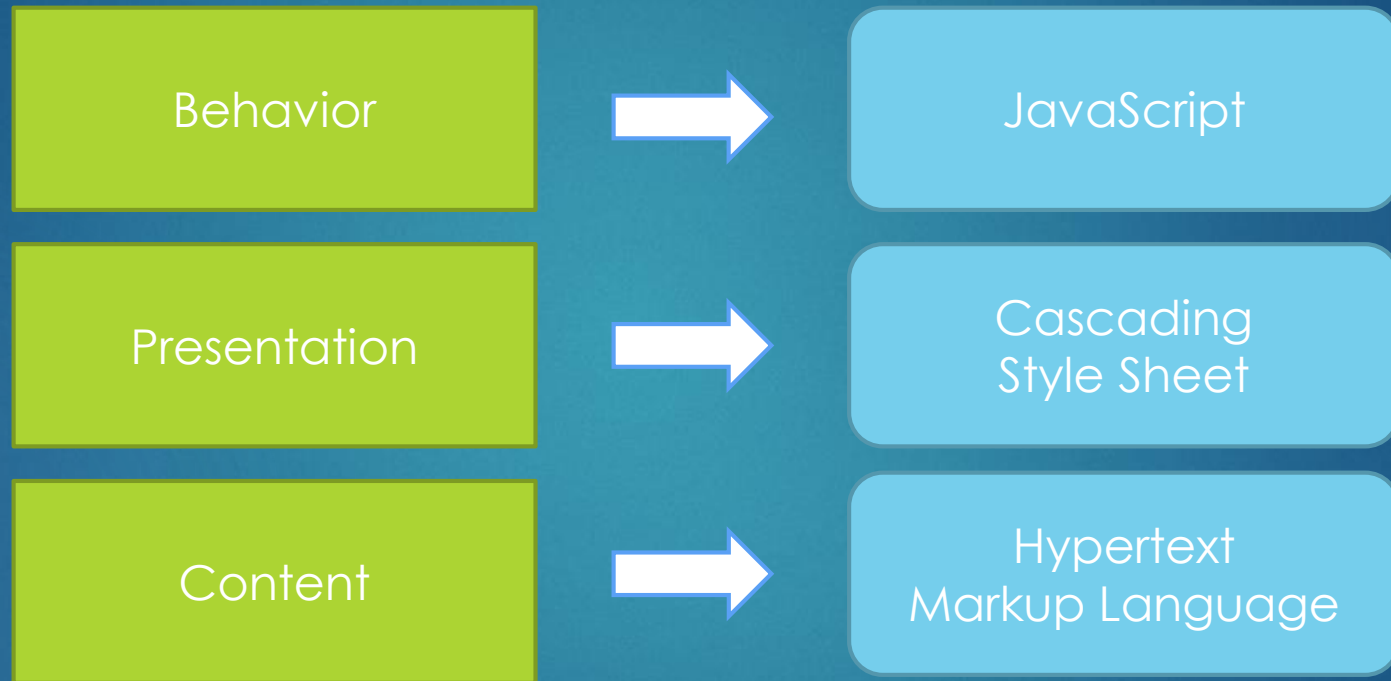

# Web Client

(HTML5, React.js)

CLIENT/SERVER COMPUTING AND WEB TECHNOLOGIES

# Web Page Layers

2

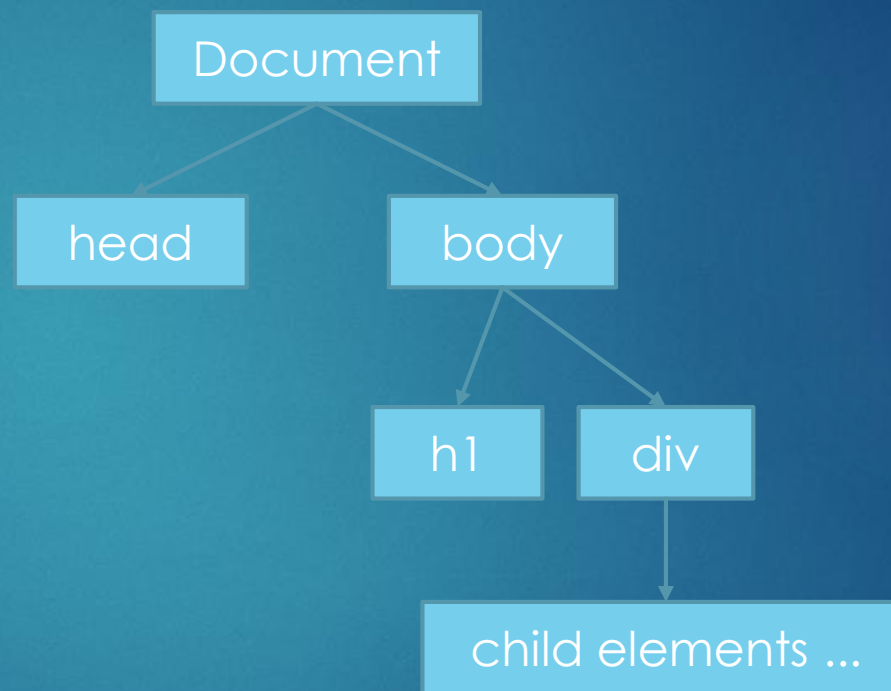

- ▶ Hypertext: A software system that links topics on the screen to related information and graphics, which are typically accessed by a point-and-click method.
- ▶ Markup Language: A set of markup tags for grouping and describing page content.

# Document Object Model

4

```
<html>  
  <head> </head>  
  <body>  
    <h1></h1>  
    <div> ... </div>  
  </body>  
</html>
```

Document Hierarchy: Parents, children and siblings

# HTML Elements

5

`<tag>Content</tag>`

- ▶ An HTML element includes both the HTML tag and everything between the tag (the content).
- ▶ Tags normally come in pairs. The first tag is the start tag, and the second tag is the end tag.
- ▶ HTML has a defined set of tag names (also called keywords) that the browser understands.
- ▶ Most elements can have attributes, which provides additional information about the element.
  - ▶ `<div class="left-nav"></div>`

# Essential Element Tags

6

## Primary Structure

html  
head  
body

## Head Elements

title  
meta  
link

## Structural Elements (block)

p  
br  
h1 - h6  
ul  
ol  
a  
img  
(div)

## Formatting Elements (inline)

em  
i  
strong  
b  
q  
blockquote  
(span)

- ▶ **Stylesheet**
  - ▶ Rules defining how an html element will be “presented” in the browser.
  - ▶ Targeted to specific elements in the html document.
- ▶ **Cascading**
  - ▶ Rules for resolving conflicts with multiple CSS rules applied to the same elements.
  - ▶ For example, if there are two rules defining the color of your `h1` elements, the rule that comes last in the cascade order will “trump” the other.

# CSS Syntax

8

```
selector {property: value;}
```

Declaration

- ▶ Every style is defined by a **selector** and a **declaration**. The declaration contains at least one property/value pair.
  - ▶ Together they are called a **CSS Rule**.

```
body {font-family: Arial, Helvetica}
```

```
p {color: #666666}
```

```
h1 {font-size: 24px}
```

```
a {color: blue}
```

# CSS Selector

9

- ▶ Type Selector

- ▶ targets an html element by name

- ▶ Id Selector

- ▶ An ID is an html attribute added to a html markup.
  - ▶ Reference that ID with a hash (#)

- ▶ `#logo { declaration }`

- ▶ `<img id="logo" src="" alt="">`

- ▶ Class Selector

- ▶ A class is an html attribute added to a html markup.
  - ▶ Reference that ID with a period (.)

- ▶ `.ingredients {declaration}`

- ▶ `<ul class="ingredients">`

p

#

.

# JavaScript

10

- ▶ JavaScript as HTML element

```
<script type="text/javascript">
```

```
...
```

```
</script>
```

*Refer to Chapter #03  
for syntaxes.*

- ▶ JavaScript as external resources

```
<script type="text/javascript" src="e.js"></script>
```

- ▶ Purposes

- ▶ Manipulate HTML DOM via document object

```
document.getElementById("logo")...
```

- ▶ Handle Event from HTML element

```
<p onclick="do_smth()"> ... </p>
```

- ▶ Implement application logics, e.g., form validations

# Libraries

11

<http://www.monolinea.com/css-frameworks-comparison/>

- ▶ CSS Framework
  - ▶ Heavyweights: Bootstrap, Foundation
  - ▶ Middleweights: Gummy, Groundwork
  - ▶ Lightweights: Pure, Base, Kube CSS
- ▶ JavaScript Library
  - ▶ DOM manipulation, animation, events, HTTP requests
    - ▶ jQuery, minified.js
  - ▶ Supports: underscore.js, moment.js
- ▶ JavaScript Framework
  - ▶ jQuery, Dojo, Ember.js, AngularJS, ReactJS, VueJS

[http://en.wikipedia.org/wiki/Comparison\\_of\\_JavaScript\\_frameworks](http://en.wikipedia.org/wiki/Comparison_of_JavaScript_frameworks)

# ReactJS

A JAVASCRIPT LIBRARY FOR BUILDING USER INTERFACES

# React features

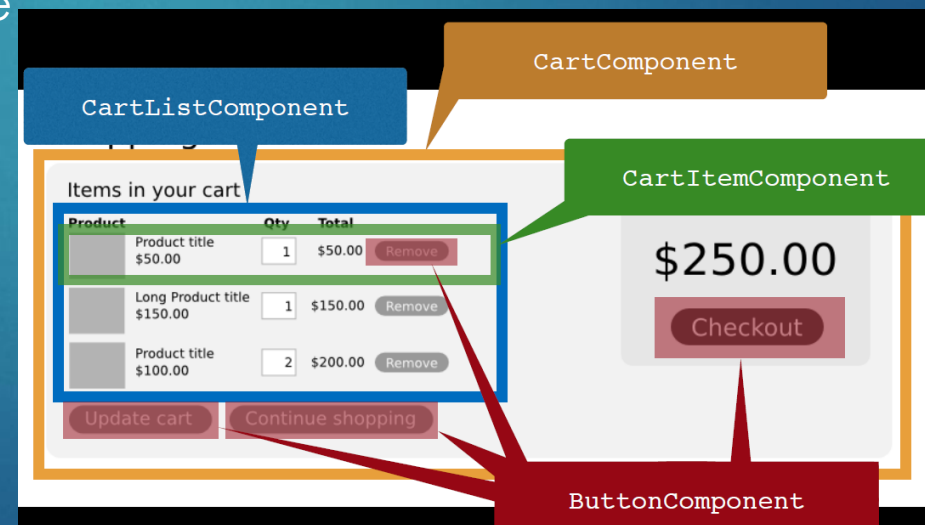

13

- ▶ JSX
  - ▶ JavaScript extension
  - ▶ Try it: <http://babeljs.io/repl>
- ▶ Components
  - ▶ Reusable, Maintainable, Testable

```
1 class Foo extends React.Component {
2   render () {
3     return (
4       <div>Foo Bar</div>
5     )
6   }
7 }

Object.getPrototypeOf(Foo).apply(this, arguments));
}
_createClass(Foo, [{
  key: "render",
  value: function render() {
    return React.createElement(
      "div",
      null,
      "Foo Bar"
    );
  }
}]);
return Foo;
}(React.Component);
```

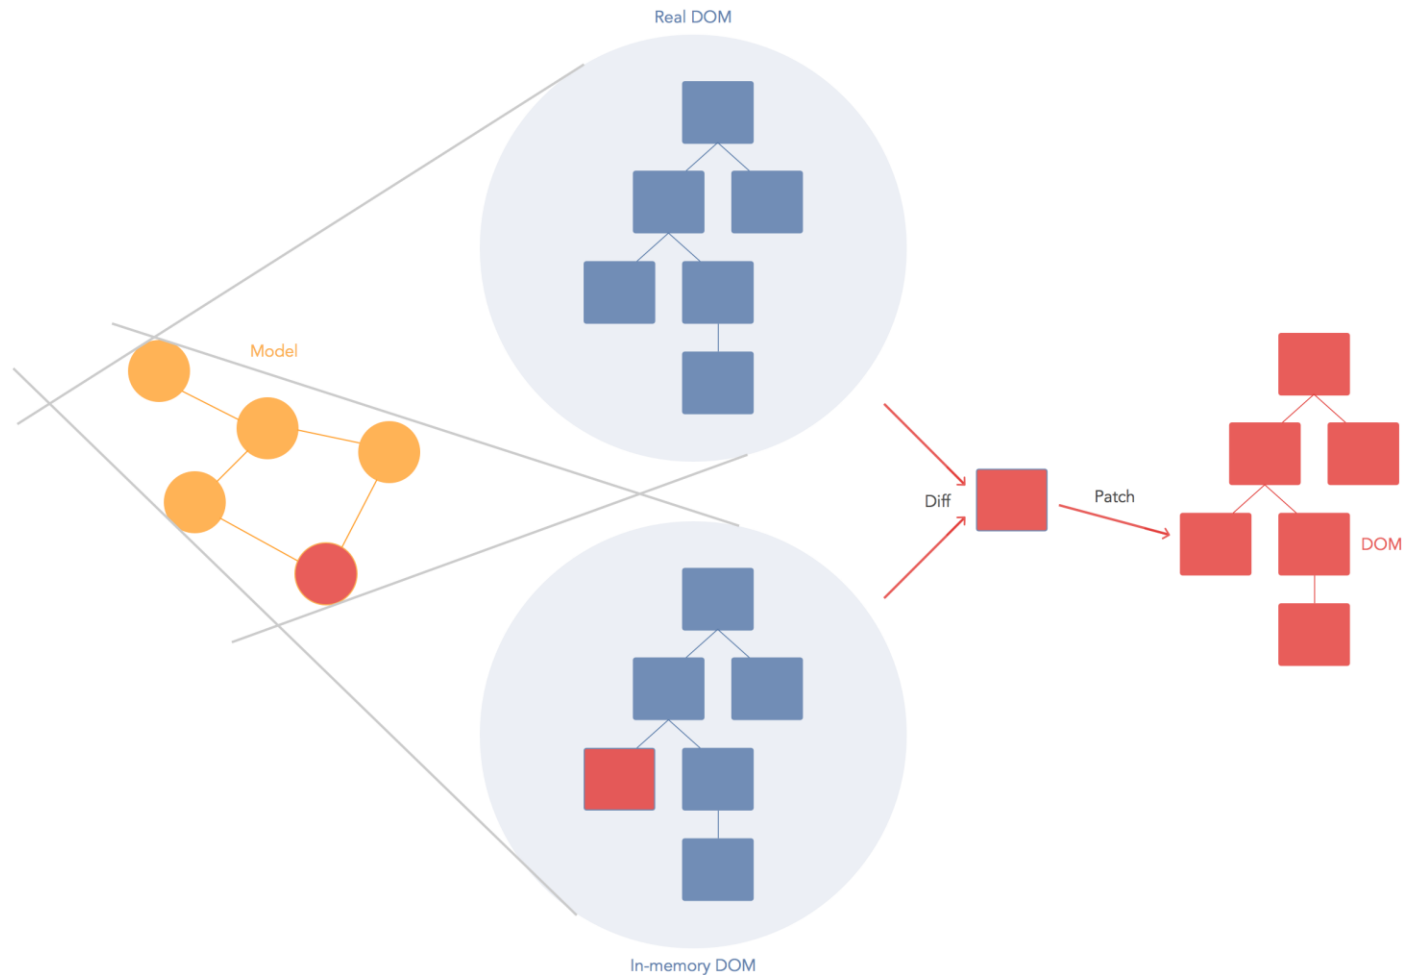

- ▶ The virtual DOM

# The virtual DOM

14

# Setup

15

- ▶ Softwares
  - ▶ node & npm
  - ▶ IDE: Web storm, VS Code, Atom, Sublime, vi
- ▶ Quick start
  - ▶ `npm install -g create-react-app`
  - ▶ `create-react-app my-app`
  - ▶ `cd my-app`
  - ▶ `npm start`

**Reference:** <https://reactjs.org/tutorial/tutorial.html>

# React: Start from scratch

16

- ▶ Prepare and create package.json:
  - ▶ `npm init -y`
- ▶ Install global package:
  - ▶ `npm install -g babel babel-cli`
  - ▶ `npm install -g webpack-dev-server`
- ▶ Add dependencies and plugins:
  - ▶ `npm install webpack webpack-dev-server --save`
  - ▶ `npm install react react-dom --save`
  - ▶ `npm install babel-core babel-loader --save`
  - ▶ `npm install babel-preset-react babel-preset-es2015 --save`

# Compiler, Server and Loaders

17

## ► create webpack.config.js

```
var config = {
  entry: './src/index.js',
  output: {
    path: '/',
    filename: 'bundle.js',
  },
  devServer: {
    inline: true,
    port: 8080
  },
  module: {
    loaders: [
      {
        exclude: /node_modules/,
        loader: 'babel-loader',
        query: {
          presets: ['es2015', 'react']
        }
      }
    ]
  }
}
module.exports = config;
```

# Compiler, Server and Loaders

18

- ▶ edit package.json

```
"scripts": {  
  "start": "webpack-dev-server --hot"  
  "test": "echo \"Error: no test specified\" && exit 1"  
},
```

**index.html**

```
<!DOCTYPE html>  
<html lang = "en">  
<head>  
  <meta charset = "UTF-8">  
  <title>React App</title>  
</head>  
  <body>  
    <div id = "app"></div>  
    <script src = "index.js"></script>  
  </body>  
</html>
```

**app.jsx**

```
import React from 'react';  
  
class App extends React.Component  
{  
  render() {  
    return (<div> Hello World!!! </div> );  
  }  
}  
  
export default App;
```

**main.js**

```
import React from 'react';  
import ReactDOM from 'react-dom';  
import App from './app.jsx';  
ReactDOM.render(  
  <App />, document.getElementById('app')  
>);
```

- ▶ npm start

Try to modify in  
app.jsx and check  
result at browser

# Component based

19

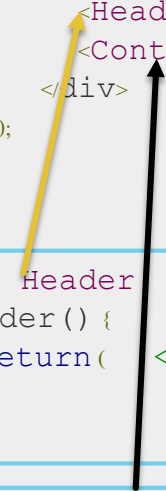

```
import React from 'react';

class App extends React.Component {
  render() {
    return(
      <div>
        <Header/>
        <Content/>
      </div>
    );
  }
}

class Header extends React.Component {
  render() {
    return( <div><h1>Header</h1></div>);
  }
}

class Content extends React.Component {
  render() {
    return(
      <div>
        <h2>Content</h2><p>The content text!!!</p>
      </div>
    );
  }
}

export default App;
```

In practical, Header and Content should be separately created and exported.

# Data passing (props vs. state)

20

- ▶ React has 2 objects of data passing in order to control data into a component
  - ▶ Props
    - ▶ Pass from parent to child components
    - ▶ Immutable
      - ▶ **Props CANNOT** be **CHANGED** inside a component
        - ▶ Single source of the truth
      - ▶ Fixed throughout the component
  - ▶ State
    - ▶ Reside within component
    - ▶ Mutable
      - ▶ State **CAN** be **CHANGED**

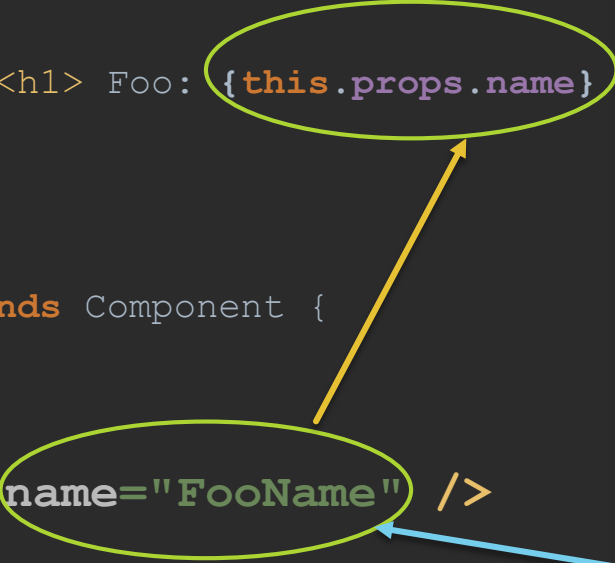

# Props: pass to a component

21

```
import React, { Component } from 'react';
class Foo extends Component {
  render() {
    return (
      <div> <h1> Foo: {this.props.name} </h1></div>
    )
  }
}

class App extends Component {
  render() {
    return (
      <div>
        <Foo name="FooName" />
      </div>
    );
  }
}

export default App;
```

The diagram illustrates the flow of props between two components. A yellow oval highlights the `name="FooName"` attribute in the `<Foo>` tag within the `App` component's render method. A yellow arrow points from this oval to another yellow oval that highlights the `{this.props.name}` expression in the `Foo` component's render method. This visualizes how the value of the `name` prop is passed from the parent component (`App`) to the child component (`Foo`).

Define a new  
property 'name'

# State: initial and update

22

```
class App extends Component {  
  constructor(props) {  
    super(props)  
    this.state = { fooState: "Foo State" }  
  }  
  
  render() {  
    return (  
      <div>  
        Message: {this.state.fooState} <br/>  
      </div>  
    );  
  }  
}
```

Initial state  
object

Read state  
object

# State: bind method to context

23

```
class App extends Component {
  constructor(props) {
    super(props)
    this.state = { fooState: "Foo State" }
    this.updateMessage = this.updateMessage.bind(this)
  }

  updateMessage(e) {
    this.setState( {fooState: "New Foo State: "
      + e.target.value })
  }

  render() {
    return (
      <div>
        <div>
          Message:
          <input type='text' onChange={this.updateMessage}/> <br/>
          {this.state.fooState} <br/>
        </div>
      </div>
    );
  }
}
```

Have to bind method to 'App' context, otherwise a new method will not be known

Define the method to update state

Trig the method

# State: automatically bind

24

```
class App extends Component {
  constructor(props) {
    super(props)
    this.state = { fooState: "Foo State" }
  }

  updateMessage = (e) => {
    this.setState( {fooState: "New Foo State: " + e.target.value })
  }

  render() {
    return (
      <div>
        <div>
          Message:
          <input type='text' onChange={this.updateMessage}/> <br/>
          {this.state.fooState} <br/>
        </div>
      </div>
    );
  }
}
```

Arrow function binds a method automatically

# State: Parent and child component

25

```
class Foo extends Component {
  render() {
    return (
      <div>
        <h3> Foo: {this.props.name} </h3>
        {this.props.fooState}
      </div>
    )
  }
}

class App extends Component {
  ...

  render() {
    return (
      <div>
        <div>
          Message:
          <input type='text' onChange={this.updateMessage} /> <br />
          {this.state.fooState} <br />
        </div>
        <Foo
          name="FooName" fooState={this.state.fooState}
          updateMessage={this.updateMessage.bind(this)}
        />
      </div>
    );
  }
}
```

The diagram illustrates the flow of state from a parent component to a child component. It features two code snippets. The first snippet, for the `Foo` component, shows it receiving `fooState` as a prop. A callout box labeled "Read 'state' as 'props'" points to the `fooState` prop in the `render` method. The second snippet, for the `App` component, shows it passing `fooState` to the `Foo` component. A callout box labeled "Pass 'state' as 'props'" points to the `fooState` prop being passed. Another callout box labeled "Update 'state' from parent but it affects to child component" points to the `updateMessage` prop, which is a bound method from the parent's stateful `render` method.

# React – AJAX Request

PROMISES: AXIOS LIBRARY

# HTTP Library: Axios

27

- ▶ Target API: <https://api.github.com/users/wwarodom>
- ▶ Example: axios
  - ▶ npm install axios --save

```
import React, { Component } from 'react';
import axios from 'axios';
```

```
const USER = 'wwarodom';
```

```
class Profile extends Component {
```

```
  constructor(props) {
    super(props)
    this.state = { data: {} }
  }
```

```
  componentDidMount() {
    axios.get(`https://api.github.com/users/${USER}`)
      .then(response => {
        this.setState({data: response.data})
        console.log(response.data)
      })
  }
}
```

Send Http request

Read object

```
render() {  
  const dataOption = Object.keys(this.state.data)  
    .map( (key,index) =>  
      <option value={index}>  
        {index+1 +'. ' +key+ ': ' + this.state.data[key]}  
      </option>  
    )  
  
  return (  
    <div>  
      <h2> Github Profile</h2>  
      <ul>  
        <li>{this.state.data.url}</li>  
        <li>{this.state.data.login}</li>  
        <li>{this.state.data['blog']}</li>  
      </ul>  
  
      <dd><select>{dataOption}</select></dd>  
    </div>  
  );  
}  
}  
  
export default Profile;
```

Pick a value
